Mice with Huntington disease develop a motor dysfunction early in the disease course. Huntington disease (HD) is a progressive, neurodegenerative disorder caused by expansion of a CAG-repeat in the HTT gene. Patients become progressively impaired in motor function, with consequent loss of independence. Although motor signs are commonly used in clinical trials as outcome measures, no preclinical model of HD has yet been fully developed. We therefore used the R6/2 transgenic mouse model of HD to examine whether changes in motor function preceded obvious neurological changes. We found that despite the early expression of motor abnormalities, the R6/2 mouse lines exhibited a significant delay in motor dysfunction compared with wild-type mice. The motor abnormalities manifested early as a reduction in the use of forepaws in the new open field, and, later on, as a general immobility in a number of testing conditions. A significantly slower decline in motor behavior was also detected in the R6/2 compared with the wild-type mice. The non-motor functions, however, appeared to remain relatively unchanged. Our results suggest that the R6/2 mice can serve as a useful model of HD, because non-motor processes do not appear to be affected until a relatively late stage of the disease.

Transcription of the DNA tumor virus SV40 genome in rabbit kidney cells. The induction of DNA synthesis in rabbit kidney (RK13) cells by SV40 infection was studied by use of a quantitative cytophotometric method. In cells infected with SV40 at a multiplicity of infection (m.o.i.) of 4 per cell, DNA synthesis was initiated at a rate of 0.51 ng/micrograms DNA-cell, as calculated by integrating the gradient of DNA synthesis over a 4-hr period. At the same m.o.i., the time required for the appearance of a clearly positive linear correlation between the uptake of 3H-thymidine and the extent of cytophotometric DNA synthesis was less than 4 hr, the same time as the appearance of a morphologically identifiable viral assembly.[The effect of laser radiation on the formation of microcalcifications in mammary glands]. The influence of laser radiation on the formation of microcalcifications in the mammary glands of Albino-Wistar rats of the first generation has been studied. The formation of microcalcifications was stimulated by both the direct laser action and by the laser effect on the blood circulation.
